(Received: November 1, 1993)

SUMMARY: Using a semiclassical approach, we have calculated electron-, proton-, and He III-impact line widths and shifts for 20 Ne VIII and 8 Na IX multiplets as a function of temperature and perturber density.

1. INTRODUCTION

In order to investigate the behavior of Stark broadening parameters along the lithium isoelectronic sequence as far as possible, we have calculated electron-, proton-, and He III- impact line widths and shifts for 20 Ne VIII and 8 Na IX multiplets, by using the semiclassical-perturbation formalism (Sahal–Bréchot 1969ab). A summary of the formalism is given in Dimitrijević and Sahal–Bréchot (1991). Discussion, analysis and comparison with the existing experimental and theoretical data, and all details of the calculations will be published in the principal article elsewhere (Dimitrijević, and Sahal–Bréchot, 1994). Since data are not linear with perturber density (N), due to the Debye screening effect, which is often important at high densities of interest for sub-photospheric layers, we will present here the data

for $N = 10^{16} - 10^{22} \text{ cm}^{-3}$ and temperatures from 200,000 K up to 2,000,000 K.

2. RESULTS AND DISCUSSION

Our results for 20 Ne VIII and 8 Na IX multiplets are shown in Table 1, for perturber densities $10^{16} - 10^{22} \text{ cm}^{-3}$ and temperatures $T = 200,000 - 2,000,000 \text{ K}$. We also specify a parameter c (Dimitrijević & Sahal–Bréchot 1984), which gives an estimate for the maximum perturber density for which the line may be treated as isolated when it is divided by the corresponding electron-impact full width at half maximum. For each value given in Tables 1 and 2, the collision volume (V) multiplied by the perturber density (N) is much less than one and the impact approximation is valid (Sahal–Bréchot,

Table 1. This table shows electron-, proton-, and He III- impact broadening parameters for Ne VIII and Na IX, for perturber densities of $10^{16} - 10^{22}$ cm $^{-3}$ and temperatures from 200,000 to 2,000,000 K. Transitions and averaged wavelengths for the multiplet (in Å) are also given. By using c [see Eq. (5) in Dimitrijević et al, 1991a], we obtain an estimate for the maximum perturber density for which the line may be treated as isolated and tabulated data may be used. The asterisk identifies cases for which the collision volume multiplied by the perturber density (the condition for validity of the impact approximation) lies between 0.1 and 0.5. Table 1 is also available in electronic form: see the editorial in Astron. Astrophys. 1992, Vol. 266, No 2, page E1 or in Astron. Astrophys. Suppl. Series 1992, Vol. 96, No 3, and Dimitrijević and Sahal—Bréchot, 1994.

1969ab). Values for $NV > 0.5$ are not given and values for $0.1 < NV \leq 0.5$ are denoted by an asterisk. When the impact approximation is not valid, the ion broadening contribution may be estimated by using quasistatic estimations (Sahal—Bréchot 1991 and Griem 1974). The accuracy of the results obtained decreases when broadening by ion interactions becomes important.

The analysis of present results and comparison with available experimental and theoretical data is given in Dimitrijević and Sahal—Bréchot (1994).

Acknowledgements — This work is a part of French—Yugoslav collaboration through the project "L'élargissement Stark des raies spectrales des plasmas astrophysiques et de laboratoire", it is also a part of the project "Physics and dynamics of celestial bodies", supported by Ministry for Science and Technology of Serbia.
